

# HOUSING PRICES IN AUSTRALIA: 1970 TO 2003

**Peter Abelson and Demi Chung**

pabelson@efs.mq.edu.au

## ABSTRACT

There have been few reliable published data for housing prices in Australia (as in many other countries). In this paper we attempt to provide an authoritative account of prices for houses and apartments (units) in Australia from 1970 to 2003. Where possible we draw directly on data from land title offices or on studies that draw on these data. The first part of the paper describes the main data sources. The main body of the paper provides best estimates of median house and unit prices and real price indices in the capital cities and in the rest of Australia. We also estimate how improvements in housing quality have influenced real house prices over time. In summary we find that there have been strong national trends, especially in recent years, and that house and unit prices have moved in similar ways. There were significant housing price booms from 1971 to 1974, from 1979 to 1981, from 1987 to 1989, and from 1996 through to 2003. After each of the first three booms, real prices tended to fall. However, in the long run real price rises outstripped falls. Consequently, real house prices rose by about 180 per cent between 1970 and 2003. Allowing for housing improvements, real prices rose by more like about 100 per cent over this period. However, both estimates give an exaggerated view of real price increases if, as we expect, there is a real house price downturn post 2003.

**JEL Classification:** R31

**Acknowledgements:** We thank the Productivity Commission for providing us with a great deal of data on housing prices, including data from land title offices around Australia. Chris Chan also provided helpful comments on a draft of this paper. We are most grateful to the National Real Estate Institute of Australia (and to the WA Branch) and to the Housing Industry Association of Australia for providing us with their data on house and unit prices. We also acknowledge the support of the Walsh Bequest run by the Economics Department, Macquarie University, which provided valuable start-up funds for this research project.

# 1 Introduction

As in many countries, there have been few reliable data on housing prices in Australia.<sup>1</sup> Until recently, public agencies published few data on housing prices and private agencies filled the gap by drawing on their own partial and usually biased data sets of residential property sales. Although the availability and quality of housing price data have improved in the last 10 to 15 years, even today the Reserve Bank (2004) finds that the data are untimely and unreliable. In this paper we describe and assess the major sources of data on housing prices since 1970, estimate price series for the major cities and for Australia as a whole, and draw out the main findings about house and apartment (unit) prices.

Section 2 describes the major data sources. Section 3 provides our estimates of median house and unit prices in the capital cities and in the rest of each state and the respective real price indices. We also estimate Australian indices for house and unit prices. Section 4 estimates the effects of improvements in housing quality on house prices over time. Section 5 summarises some major features of house and unit prices since 1970. A lengthy appendix provides detailed price data for each city and state from the alternative data sources.

## 2 Data Sources

In Australia in 2001, there were 7.1 million residential dwellings of which 75 per cent were separate houses, 13 per cent were units and 12 per cent were other forms of housing (terraces, semi-detached, town houses, etc.). Most housing price data relate to houses; some to units; almost none to other dwellings. We describe below the main primary and secondary data sources.

### Primary sources

There are three main primary sources of data on housing prices:

- Government land title offices<sup>2</sup>,
- The Real Estate Institute of Australia, and
- The Commonwealth Bank of Australia.

---

<sup>1</sup> We use the term ‘housing’ to refer to all forms of dwellings, including houses and apartments.

<sup>2</sup> The location of the land title office varies according to the state or territory and may be in a Valuer-General Office, Department of Land, Department of Housing or some other Department.

**Land title offices** (LTOs) in all states and territories receive data on all property transactions based on settlement dates and are the best primary source of property price data. However, the LTOs vary greatly in their analysis and distribution of price data. Only the NSW LTO regularly publishes summary statistics on housing prices ([www.housing.nsw.gov.au](http://www.housing.nsw.gov.au)). Estimates of median prices now go back to 1980 but these data became available only recently. The Victorian and South Australian LTOs can provide house price data from the early 1970s; the Northern Territory from 1980; Queensland from 1986; Western Australia from 1990.<sup>3</sup> However, most of these LTOs supply data to other parties only on a commercial and restricted basis. None publishes summary price statistics on a regular and timely basis. The tables in the Appendix show the price data available from LTOs. As indicated, some of the statistics shown are based on external analyses of land title data. It should also be noted that there are few LTO-based statistics for unit prices or for non-capital city prices.

The second main source of primary data is the **Real Estate Institute of Australia** (REIA). The REIA has estimated median house and unit prices in most capital cities each quarter from 1980 and provided these estimates to its members and to others for non-commercial purposes. Before the September quarter 1998, these widely cited figures were based on sales that members reported to the state or territory branch of the REIA, again based on settlement dates. These were a large part of dwelling sales but not necessarily representative. However the bias, if any, in the data is not known. From September quarter 1998, the REIA reports that it has obtained most of its data from LTOs, except in Victoria where it still relies on sales recorded by REIA members (which range from 6,000 to 10,000 per quarter).<sup>4</sup> Thus the REIA is no longer a second primary source and its published series of dwelling prices is based on two different primary sources.<sup>5</sup>

Since 1984, the **Commonwealth Bank of Australia** (CBA) has estimated median house prices based on sales for which it provides finance in both capital cities and the rest of each state. Unlike the other two series, the prices are recorded when purchase is agreed rather than at settlement. The CBA figures are published regularly by the Housing Industry of Australia. However, they are unlikely to be a representative set of houses. As will be seen, CBA housing prices are often different from other price series.

---

<sup>3</sup> We are not aware of any systematic analysis of ACT or Tasmanian land title data.

<sup>4</sup> REIA statement in correspondence with authors. However, there are some differences between REIA estimates and government agency housing prices supplied to us by the Productivity Commission.

<sup>5</sup> Although drawing on the same primary data source, REIA estimates of median house prices are not always the same as other estimates that draw on land title data.

From time to time, there are other primary sources of housing price data. A noteworthy example is the publication of the prices of auction sales in the 1960s and 1970s by some newspapers. Obviously price estimates derived from these sale figures may be poor guides to price levels, but perhaps less so as to percentage changes. However, they provided the basis of the major series of house prices estimated then by a consulting company (**Bis-Shrapnel**). The Commonwealth Treasury draws on them for part of its long-run quarterly house price series.

### **Secondary sources**

The most important secondary source of data on house prices is the **Australian Bureau of Statistics** (ABS). The ABS has published estimated *quarterly indices* for house prices for eight capital cities separately and combined in a weighted series since 1986 (see *House Prices Indexes: Eight Capital Cities, Cat. No. 6416.0*).<sup>6</sup> However, the ABS does not publish actual house prices or any price information for units. For most cities, the ABS draws on a complete set of house transactions provided by LTOs. Where these data are not available, the ABS draws on REIA data.<sup>7</sup> Unlike most other agencies, the ABS attempts to control for quality changes by stratifying houses by area within a city and by size (three or four bedrooms). For Sydney, Melbourne, Brisbane and Adelaide, the ABS estimates *median* prices for each area using a ‘trimean’ method and after excluding outliers.<sup>8</sup> For Perth, Hobart, Darwin and Canberra, the estimated average price is the *mean* of all sales in each area, excluding outliers. The Bureau then estimates a weighted average price for the cities and the price movement between periods. The ABS does not control for improvements to housing in the form of alterations and additions, which are often substantial. The Bureau estimates the national capital city index by weighting the cities on the basis of finance commitments.

Private firms or analysts also provide housing price information. RBA (2004) cites two major current providers. Drawing on data from LTOs, **Residex** has reportedly estimated property prices indices for Brisbane, Melbourne and Sydney from 1978.<sup>9</sup> Residex attempts to exclude quality change effects by basing its indices only on prices changes between successive sales of the same property. However, this reduces the size of the sample and does not allow for alterations and additions. Also, the series is subject to revision as more properties are added to the series. **Australian Property Monitors** (APM) estimates prices for seven capitals also

---

<sup>6</sup> The ABS (Cat. 6416.0) also provides indices for the costs of project homes. But these are construction costs, which exclude land values and landscaping costs.

<sup>7</sup> Correspondence with the ABS. The ABS did not indicate the cities for which it draws on REIA data.

<sup>8</sup> The trimean method involves estimating the median prices for three price groups (top, middle and bottom) and giving twice as much weight to the middle group.

<sup>9</sup> Our comments on Residex and APM draw on RBA (2004). Neither Residex nor APM responded to our requests to supply data for this paper.

based on data from LTOs, based on the date of contract rather than date of settlement. As far as we are aware, APM has not estimated a historical price series.

In an early study of house prices, Abelson (1982) reviewed all available data and estimated quarterly house prices in the capital cities in the 1970s. This drew on official and other sources, including an obscure clerk in the tax office in Tasmania who had assembled quarterly house price data for Hobart. In 1991, consultants Applied Economics and Travers Morgan produced a major review of house prices in Adelaide, Melbourne and Sydney, which drew on price data from LTOs.

In preparing its report on *First Home Ownership*, the Productivity Commission (2004) developed house price series from 1980 for most capital cities (from 1970 for Sydney and Melbourne), which drew on several of these sources. For recent years, it drew on LTO data for Sydney, Melbourne, Adelaide and Brisbane and on REIA data for Perth, Canberra, Darwin and Hobart. The Commission published the results in graphical rather than in numerical form. The Commission did not estimate or cite unit prices.

Mention should also be made of the Commonwealth Treasury's estimated unpublished quarterly index for house prices in Australian capital cities from 1959-60 to the present. This index is a weighted figure based on house prices in Sydney, Melbourne, Brisbane, Adelaide, Perth and Canberra. This series is based on ABS data from December quarter 1985 to the present, on REIA data from 1980 to September quarter 1985, and on Bis-Shrapnel data back to 1960. This index is discussed further below.

In summary, there are far more data on detached houses than on units. For some types of housing, there are no data. Most data relate to capital cities but there are some data for the rest of the states. Only the CBA has produced price data for new houses including land. The only agency that attempts to control for housing quality is the ABS, which has estimated house price indices for the capital cities since 1986, but it does not publish house prices. Also, its control for quality is limited as it does not allow for alterations and additions. The REIA provides the longest continuous series back to 1980 (although it now draws on LTPO data) and the best price data for units. Generally, LTO price data are to be preferred where these are available.

### 3 Preferred Housing Price Series

The Appendix contains housing prices for each capital city and jurisdiction from 1970 (or later year as data are available) to 2003. For each state there are six tables:

1. Annual median house prices for the capital city
2. Annual median house price indices for the capital city (nominal indices)
3. Annual median unit prices for the capital city
4. Annual median unit price indices for the capital city (nominal indices)
5. Annual median house and unit prices for the rest of the state
6. Annual median house and unit price indices for the rest of the state (nominal indices)

For the two territories the first four tables are provided.

Where possible the tables in the Appendix show prices series based on LTO, REIA and CBA data.<sup>10</sup> The nominal indices for house prices include ABS indices from 1986.

It may be observed that, from 1990 to 2003, housing prices based on the REIA and CBA series tended to rise by more than prices derived from LTO data. Adelaide was the only exception. We have no explanation for these differences.

On the other hand, as would be expected, where comparisons are possible the ABS indices generally rose by less than the other housing price indices. An exception was Sydney where the ABS index rose by more than the LTO-based index but by less than the REIA and CBA indices. This suggests that the ABS is partially successful in eliminating quality changes. However, the differences between the indices are usually small and, as discussed below, all reported house prices embody significant quality changes.

Our preferred best estimates of median house and unit prices for the capital cities and the rest of the states from 1970 to 2003 are shown below. Tables 1, 3 and 5 show estimated prices. Tables 2, 4 and 6 show the corresponding real price indices, with 1990 treated as 100.0.

Footnotes to the respective tables describe the assumptions on which the estimates are based. Where possible we draw directly on LTO data or on analyses which draw on LTO data.

---

<sup>10</sup> It should be noted that, in lieu of an actual median house price in a year, in some cases the estimated annual median price is the mean of the median prices in the four quarters of the year. This is not likely to be precisely the median house price in the year, but is probably close to it.

Where such data are not available, notably in earlier years, we splice on other earlier year data using estimated rates of changes from the best available alternative series.

The real price index figures for each city or state are obtained by deflating or inflating the prices by the weighted consumer price index for all the capital cities. We estimate our Australian price indices for houses and units by weighting the estimated real indices according to the number of houses or units in each city as shown in the 1991 Census. For houses, the weights are Sydney (0.30), Melbourne (0.29), Brisbane (0.14), Adelaide (0.10), Perth (0.11), Hobart (0.02), Canberra (0.03) and Darwin (0.01). When data for some cities are not available in the earlier years, we re-weight the cities according to available data. For units, the weight is much higher for Sydney (0.51). Melbourne (0.25) and Brisbane (0.10) have significant weights. The other cities have very low weights.

Table 1 also shows the real Australian Treasury house price index. The Treasury index is a weighted average of prices in six cities: with weights drawn from the 14<sup>th</sup> CPI series namely Sydney (0.36), Melbourne (0.29), Brisbane (0.13), Adelaide (0.08), Perth (0.11) and Canberra (0.03). Our index in Table 1 is the average quarterly Treasury figure converted into a real index with 1990 again = 100.

## **4 Effects of Housing Quality**

Houses have many attributes, including size, garages and swimming pools, central heating and air conditioning, kitchens of various qualities, and so on. Generally the quality of dwellings rises over time. For example, the size of new homes has increased over many years by around 2 per cent per annum. Between 1984-85 and 2002-03, the average floor area of new houses in Australia rose by 40 per cent (from 162 m<sup>2</sup> to 227.3 m<sup>2</sup>) and the average floor area of other new dwellings rose by 35 per cent (from 99.2 m<sup>2</sup> to 134 m<sup>2</sup>).<sup>11</sup>

As we have seen, the ABS attempts to control for quality changes by stratifying houses by area within a city and by size (three or four bedrooms). This ensures a constant composition of the housing stock in the ABS index with respect to the number of bedrooms. But it does not allow for changes in the physical or locational attributes of particular properties. Physical attributes reflect home improvements. Locational attributes reflect neighbourhood or infrastructure improvements.

---

Sources: ABS, Cat. 5204.0. Value of housing stock estimated – see text.

Of special interest for this paper are improvements to existing dwellings that make up 98 per cent of the housing stock at any point in time. In addition to repairs and maintenance to dwellings to maintain housing quality, households spend regularly spend about 2 per cent of GDP on dwelling improvements (alterations and additions) – see Table 7. Indeed in recent years, expenditure on alterations and additions has risen to 2.5 per cent of GDP.

More importantly, Table 7 (column 2) provides estimates of annual expenditure on dwelling improvements in relation to the value of the dwelling stock at the end of the financial year. Our estimates of the value of the dwelling stock are based on our estimates of the value of the stock of houses, units and other dwellings in each state in June 1991 as shown in the 1991 population and housing census. We inflated the estimated median values for these housing types by 9 per cent to reflect typical (observed) differences between median and mean values. The estimated values for the housing stock in other years allow for an average 1.75 per cent change in the quantity of the stock each year and for estimated changes in nominal dwelling

prices. For the 24 years, 1979-80 to 2002-03, we find that expenditure on alterations and additions averaged 1.02 per cent of the value of the housing stock.

We conclude that the quality of the established housing stock rises by about 1 per cent per annum on average. Expenditure on alterations and additions does not include expenditure on fittings (which tend to improve) or any non-market household or black economy time spent on maintaining or improving dwellings. And, as noted, the size of new buildings is increasing at well over 1 per cent per annum. Moreover, although expenditure on alterations and additions varies a little in relation to GDP, the relationship is remarkably steady except for the most recent years. It might be anticipated that expenditure on alterations and additions is disproportionately on houses rather than on units, which are less amenable to alterations, but we have no evidence on this.

Before estimating the impacts of these quality changes on dwelling prices, we also consider possible differences between the states. Table 8 shows the proportion of dwellings in each state and the percentage of expenditure on alterations and additions in each state in calendar years 2001 and 2002. The table shows that broadly speaking expenditure on alterations and additions matched the proportion of dwellings in each state. In relation to dwellings, expenditure on alterations was high in Queensland and low in Adelaide and Tasmania.

Table 9 provides revised estimates of real house price indices for each capital city for 1980 and 2003 (holding 1990 = 100.0) on the assumption that alterations and additions accounted for a one per cent per annum increase in the median value of houses in each city. This significantly reduces the real increases in house prices. However, given the extraordinary increases in house prices that occurred between 1980 and 2003, there remained substantial real house price increases in all cities over this period.

**Table 8 Allocation of expenditure on alterations and additions**

State / Territory	Percentage of dwellings	Percentage of expenditure on AA	
		2001	2002
NSW	33	30	31
Victoria	25	28	26
Queensland	19	22	24
S. Australia	8	6	6
W. Australia	10	10	9
Tasmania	3	1	1
ACT	2	2	2
N. Territory	1	1	1
Total	100	100	100

## 5 Housing Prices: Main Findings

In this section we summarise some main findings about house and unit prices in capital cities and housing prices in the rest of Australia.

### House prices in capital cities

In Table 2 (and in Figure 1) we show two real house price indices for Australian capital cities: one estimated by Treasury and one that we derived as described above, but with no allowance for alterations and additions. Not surprisingly, the indices are similar, especially since the mid-1980s. The correlation is 0.995 for the period from 1986 to 2003 but only 0.774 for 1970 to 1985.<sup>12</sup> We estimate a slightly higher price spike in 1974-75 and a slightly smaller one in 1980-81. As we have noted, the two series use different weights, with the Treasury giving more weight to Sydney houses. We have not seen the 1970s' house price data on which the Treasury index is based and so cannot explain the differences in this decade.

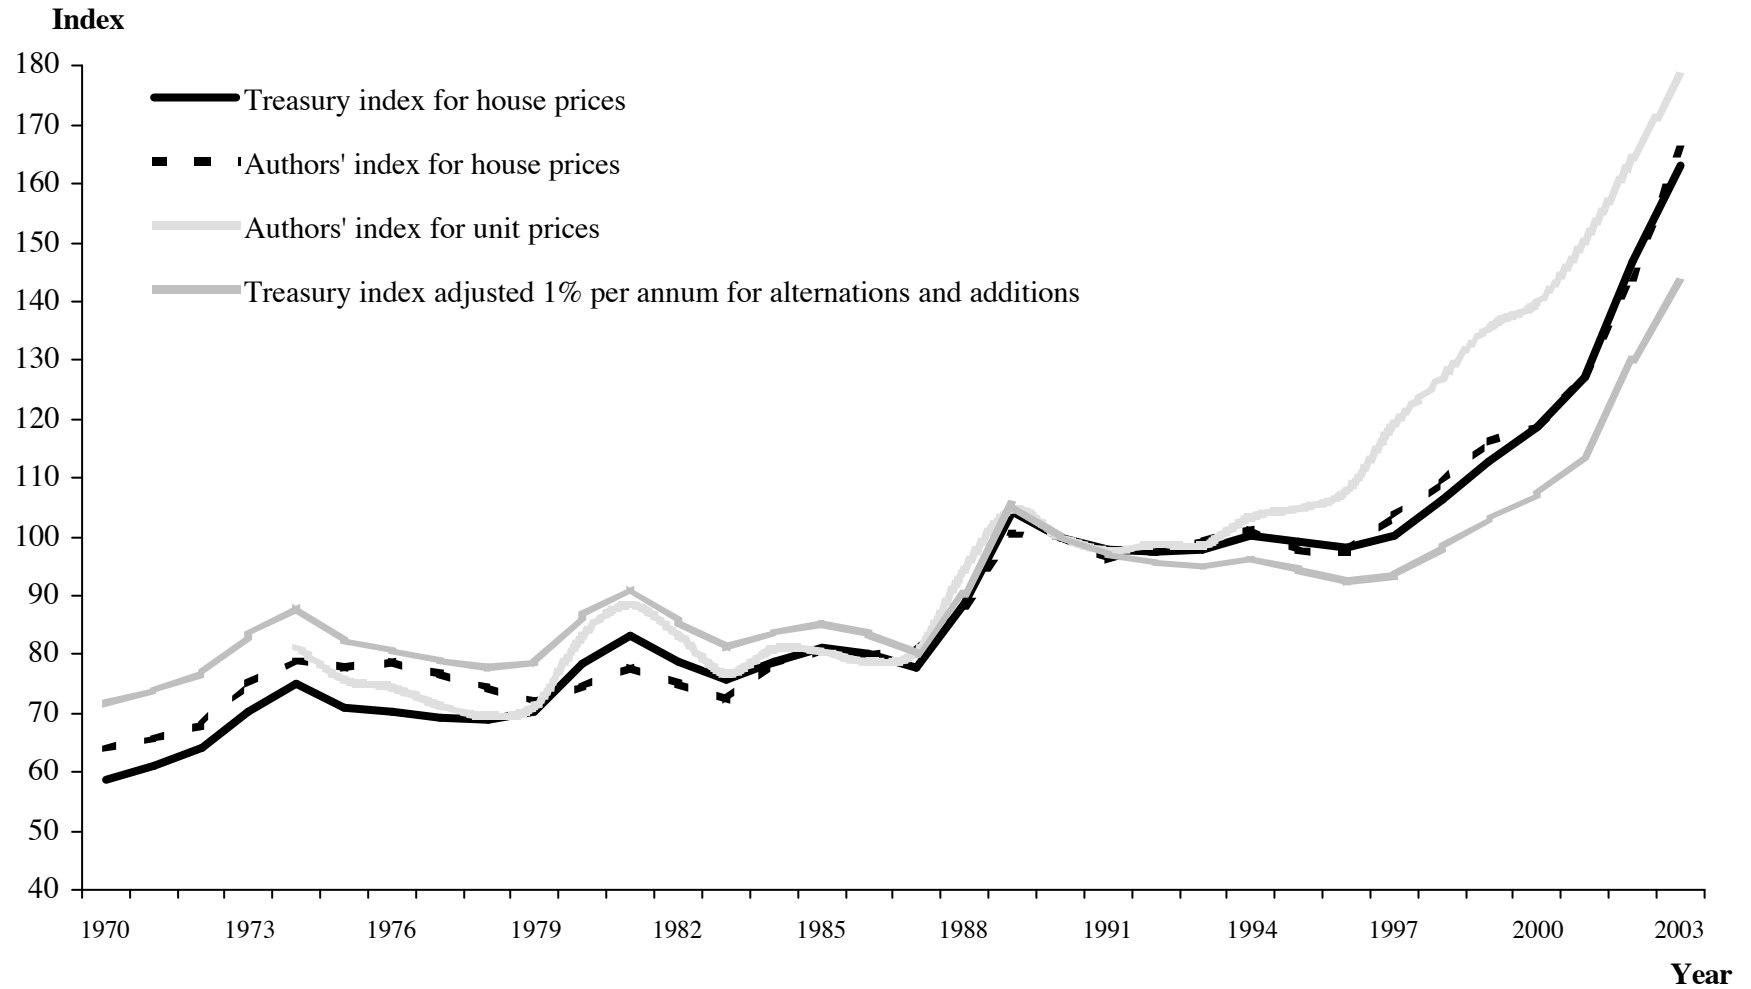

Both indices show significant house price booms from 1971 to 1974, from 1979 to 1981, from 1987 to 1989, and from 1996 through to 2003 (much the most prolonged price boom). After each of the first three booms, real prices tended to fall. However, in the long run real price rises were greater than the falls, resulting in a long-run real price increase. Real house prices rose by about 180 per cent (nearly tripling) between 1970 and 2003. However this may be a false comparison as we have not yet seen the likely downturn post the 1996-2003 boom (see Abelson, Chung and Milunovich, 2004).<sup>13</sup>

<sup>12</sup> The correlation for the whole period 1970 to 2003 is 0.99.

<sup>13</sup> To avoid trough to peak comparisons, the Productivity Commission (2004) estimated time trend growth rates which provide lower long-term annual growth rates.

**Figure 1**

**Housing price indices 1970-2003**

In Figure 1, we also show real house prices on the assumption that alterations and additions accounted for a one per cent increase in house prices per annum. On this basis, real house prices would have approximately doubled between 1970 and 2003 (again possibly an unrealistic end-year comparison).

Contrary to some popular views, cities have generally experienced similar changes in house prices, especially in recent years. Between 1990 and 2003, ignoring alterations and additions, real house prices rose between 47 per cent and 77 per cent in all cities, compared with an Australian figure of about 64 per cent. Even over a longer period, the major cities exhibited similar price movements. From between 1970 and 1973 (depending on data availability) to 2003, the following correlations are observed: Sydney-Melbourne (0.925); Sydney-Brisbane (0.916); Melbourne-Adelaide (0.921), Melbourne-Perth (0.811).

However, the smaller and more outlying cities deviated more from the norms. For example, house prices in Perth fell in real terms in the 1971 to 1974 house price boom, possibly because Perth experienced an earlier real increase with the 1969-71 stock mining boom in the West. Canberra experienced major house price booms after Labor party general election wins in 1972 and 1983 (the latter boom a departure from national trends). Also real house prices in Perth, Hobart and Canberra rose in the early 1990s when real prices in other cities were falling.

### **Unit prices in capital cities**

House and unit prices also exhibited similar trends (see Figure 1). The unit price index rose slightly more in recent years due to the high weighting of Sydney in the unit index. Real unit prices boomed between 1978 and 1981, 1986 and 1990, and from 1993 though to 2003.<sup>14</sup> There was a high correlation (0.982) between our Australian house and unit price indices from 1974 to 2003. High correlations can also be observed between house and unit prices *within* Sydney and *within* Melbourne. Such high correlations would not necessarily be expected as houses usually contain more land value than do units.

Also, unit prices in the major cities moved in broadly similar ways. The correlations between Sydney and Melbourne unit prices from 1974 to 2003 and between Sydney and Brisbane prices from 1980 to 2003 were 0.893 and 0.942 respectively.

---

<sup>14</sup> Real unit prices also boomed in Sydney in the early 1970s (we do not have data for other cities in this time).

## **Rest of Australia**

In recent years house prices in the rest of Australia have risen in a remarkably similar way to those in cities. Between 1990 and 2003, real prices in the rest of Australia rose by an estimated average of 67 per cent compared with real prices in the cities that rose by an estimated average of 63 per cent. Again the main movements in prices were similar over time. Also, prices rose in broadly similar ways in all states, though slightly more in NSW, Victoria and Western Australia than in South Australia, Queensland and Tasmania.

## **6 Conclusions**

In this paper we have attempted to provide an authoritative account of housing prices in Australia from 1970 to 2003. Where possible we have drawn on data from land title offices around Australia, though this has not been entirely feasible. The paper provides the key summary data and the Appendix gives the data in detail.

There are strong national trends with price changes in the major cities quite highly correlated. Also unit prices in cities were highly correlated with house prices in cities and house price movements outside cities have reflected price movements in cities in recent years.

There were significant house price booms in most of Australia from 1971 to 1974, from 1979 to 1981, from 1987 to 1989, and from 1996 through to 2003. After each of the first three booms, real prices tended to fall. However, in the long run real price rises outstripped falls. Consequently, real house prices rose by about 180 per cent between 1970 and 2003. Allowing for housing improvements, real prices rose by more like about 100 per cent over this period. Of course, both estimates give an exaggerated view of real price increases if, as we expect, there is a real house price downturn post 2003.
